ACHELION CAPITAL MANAGEMENT, LLC

ARMS Module Specification

Addendum 2 to FSD v1.1

Module C: Customer Dependency Map (CDM)
Module D: Thesis Dependency Checker (TDC)

For: Josh Paul — Lead Developer
Version: 1.0 — March 26, 2026
Classification: CONFIDENTIAL — GP and Development Use Only

These two modules close the cross-sector signal propagation gap. The gap was identified when the daily monitor failed to surface MU's downstream exposure to the Google antitrust ruling. That class of risk — legal or regulatory impairment of a named demand driver — is now systematically detected.

"The system catches what the PM should not have to catch."

0. Why These Two Modules Exist — The Incident That Created Them

On March 26, 2026, the daily ARMS monitor failed to surface a material risk to MU's thesis. The PM caught it. The system did not. These modules ensure that class of failure does not recur.

The Google antitrust case — specifically the DOJ pursuing structural remedies including potential Chrome divestiture and restrictions on default search agreements — creates direct downstream risk to Micron's conviction thesis. The connection runs three hops: Google faces legal constraints → Google's AI infrastructure capex is impaired → HBM memory demand from Google weakens → MU's primary bull case thesis takes a direct hit.

The daily monitor flagged MU as OK. It should have flagged WATCH with a cross-reference alert citing the Google antitrust development as a named demand driver under material legal uncertainty. It did not — because the architecture has no mechanism to connect a legal proceeding against a named entity to the portfolio positions that depend on that entity for thesis validation.

This is not a price alert failure. MU's price was stable. This is a thesis integrity failure — the system was not watching whether the reasons we own what we own are still intact. That is a more dangerous blind spot than a price alert miss, because thesis deterioration precedes price deterioration. The PM who catches it early preserves capital. The PM who catches it late is managing a loss.

The Google-MU connection also has broader FEM implications. NVDA, AVGO, ANET, and MRVL all have material Google revenue exposure. A single legal proceeding against one hyperscaler propagates risk across five positions simultaneously. The Customer Dependency Map makes that propagation visible in real time. The Thesis Dependency Checker makes it actionable.

These two modules together form the thesis integrity layer of ARMS — the system that continuously audits whether the reasons we own each position are still structurally intact, independent of price performance.

MODULE C — CUSTOMER DEPENDENCY MAP

CDM — Cross-Sector Signal Propagation Layer

1. Module C Overview

File	src/config/position_dependency_map.py — new config file src/engine/cdm.py — new module
Tier classification	Tier 0 — monitoring and alerting only. No execution. Feeds TDC (Module D) with cross-reference signals.
Build time	1 day — config population is manual; the monitoring logic is simple pattern matching against named entities.
Dependencies	News feed (free — NewsAPI or EDGAR RSS) · position_dependency_map.py config · session log
Ongoing cost	$0 — free news feeds sufficient for named entity monitoring
Feeds into	Thesis Dependency Checker (Module D) · daily monitor WATCH flags · FEM cross-reference layer
Key insight	This module does not predict outcomes. It propagates known facts — a legal ruling, a regulatory filing, an earnings warning from a named demand driver — to every dependent position immediately. Speed and completeness of propagation is the entire value.

1.1 The Dependency Map Structure

The dependency map is a configuration file that encodes, for each portfolio position, the named entities whose health is material to the thesis. It is populated manually by the PM when a position enters the book via SENTINEL and updated when the thesis evolves. It is the machine-readable version of the Gate 2 SENTINEL answer: who are the non-optional customers, platforms, or infrastructure providers this company depends on?

The map has three dependency categories. Primary demand drivers are the entities that directly purchase this company's products or services at material scale. Thesis enablers are the entities whose continued operation or investment is necessary for the thesis to hold — a hyperscaler that is not yet a customer but whose capex trajectory the thesis depends on. Regulatory counterparties are the entities whose legal or regulatory status directly affects the position — a government customer, a platform this company distributes through, or a regulator with jurisdiction over this company's market.

Architecture AB — current dependency map

The following table is the initial population of the CDM for the current equity book. Josh populates this as the config file on Day 1. The PM reviews and confirms accuracy. It is a living document — updated every time a position is added, removed, or when the thesis evolves.

Ticker	Primary demand drivers	Thesis enablers	Regulatory counterparties	Alert sensitivity
TSLA	None (direct consumer + fleet)	US EV tax credit policy, SpaceX/xAI ecosystem	NHTSA (autonomy), SEC (Musk disclosures), DOE (energy storage)	HIGH — regulatory and Musk-related events
NVDA	Microsoft, Google, Amazon, Meta, Oracle	US-China export control policy, TSMC capacity	BIS (export controls), EU antitrust, Senate Commerce Committee	CRITICAL — export controls and hyperscaler capex events
AMD	Microsoft, Google, Amazon, Meta	TSMC capacity, x86 ecosystem health	BIS (export controls), EU antitrust	HIGH — export controls and hyperscaler events
PLTR	US DOD, US DHS, US intelligence community, NATO allies	US defense budget, AI executive orders	DOD contracting, ITAR, FedRAMP	HIGH — defense budget and government AI policy events
ALAB	Microsoft, Google, Amazon, Meta (hyperscaler PCIe/CXL connectivity)	AI data center build cycle, PCIe Gen 6 adoption	SEC (insider trading — active flag)	CRITICAL — hyperscaler capex and insider activity
MU	Microsoft, Google, Amazon, Meta (HBM buyers), Samsung/SK Hynix competitive dynamic	AI training and inference demand, HBM3E adoption cycle	DOC (China sales restrictions), CHIPS Act compliance	CRITICAL — hyperscaler capex and export control events
ANET	Microsoft, Meta, Google, Amazon (hyperscaler networking)	AI data center networking upgrade cycle	EU antitrust, FCC	HIGH — hyperscaler capex events
AVGO	Google, Apple, Meta (custom ASICs), OpenAI	TSMC capacity, custom silicon adoption vs NVDA	EU antitrust (Broadcom-VMware remedies ongoing), BIS	HIGH — TSMC capacity and antitrust events
MRVL	Microsoft, Google, Amazon (custom silicon + networking)	5G infrastructure build, cloud networking upgrade	BIS (export controls), EU antitrust	HIGH — hyperscaler and export control events
ARM	Apple, NVDA, Qualcomm,	Mobile and AI chip design adoption,	UK CMA, EU antitrust, SoftBank relationship	MEDIUM — licensing dispute

	Samsung, Google (licensing)	RISC-V competitive threat		and antitrust events
ETN	Data center operators, utilities, hyperscalers (power infrastructure)	US data center build cycle, grid modernization policy	FERC, state utility regulators, EPA	MEDIUM — energy policy and grid regulation events
VRT	Hyperscalers, colocation data centers, telecom operators (cooling + power)	AI data center build cycle, liquid cooling adoption	None material at current scale	MEDIUM — data center build cycle events

1.2 Named Entity Alert Logic

CDM runs a continuous named entity recognition scan against the incoming news feed, SEC EDGAR filings, and regulatory announcements. When a named entity in the dependency map appears in a new filing or news item, CDM classifies the event type and propagates an alert to every position that lists that entity as a dependency.

Event type	Examples	Alert severity	Action triggered
Legal ruling or judgment	Antitrust ruling, patent judgment, regulatory enforcement action	CRITICAL	Immediate TDC thesis review queued for all dependent positions
Regulatory filing or proceeding	DOJ remedy proposal, SEC investigation, export control rulemaking	HIGH	TDC review queued within 24 hours for all dependent positions
Earnings warning or guidance cut from named driver	Hyperscaler reduces capex guidance, announces data center delay	HIGH	TDC review queued within 24 hours. FEM re-run triggered.
Leadership change at named driver	CEO departure, CFO change at primary customer	MEDIUM	TDC flags for next weekly review cycle
M&A announcement involving named driver	Named driver acquired, merged, or divested	HIGH	TDC review queued within 24 hours. Dependency map update required.
Positive development for named driver	Named driver expands capex, announces new product cycle	LOW	No alert — positive dependency events do not require thesis review. Noted in session log.

1.3 The Google-MU Case Study — How CDM Would Have Worked

This is the exact failure the CDM closes. Walk through it precisely so Josh understands the design intent.

On the morning of March 26, 2026, the following events were present in public data: (1) Google antitrust ruling — DOJ pursuing structural remedies including Chrome divestiture. (2) MU conviction thesis depends on HBM demand from Google as a named primary demand driver.

With CDM live, the sequence would have been:

1. CDM ingests news feed. Named entity recognition identifies 'Google' and 'Alphabet' in antitrust articles.
2. CDM looks up 'Google' in the dependency map. Finds: MU (primary demand driver), NVDA (primary demand driver), AMD (primary demand driver), ALAB (primary demand driver), ANET (primary demand driver), AVGO (thesis enabler), MRVL (primary demand driver).
3. CDM classifies event type: LEGAL_RULING. Severity: CRITICAL.
4. CDM propagates CRITICAL alert to all seven positions simultaneously.
5. Each alert reads: 'Named demand driver GOOG/Alphabet subject to antitrust remedy proceedings. Structural remedies under consideration may impair AI infrastructure capex. Thesis dependency review required.'
6. TDC (Module D) receives the propagation signal and queues a thesis integrity review for each dependent position within the next 6 hours.
7. Daily monitor surfaces a DANGER alert in the alerts section: 'CDM: GOOG legal ruling affects 7 positions. TDC thesis review queued. See dependency cross-reference.'

Total time from event to PM alert: under 30 minutes from ingestion. The PM does not need to be reading broadly. The system is reading broadly for them and routing the signal to exactly the positions it affects.

1.4 Config File Specification

```
# src/config/position_dependency_map.py
# Updated by PM when positions enter or exit the book via SENTINEL

POSITION_DEPENDENCIES = {
    'MU': {
        'primary_demand_drivers': [
            'Microsoft', 'Google', 'Alphabet', 'Amazon', 'AWS',
            'Meta', 'Oracle'
        ],
        'thesis_enablers': [
            'TSMC', 'HBM demand cycle', 'AI training infrastructure'
        ],
        'regulatory_counterparties': [
            'DOC', 'BIS', 'CHIPS Act', 'China export restrictions'
        ],
```

```
            'alert_sensitivity': 'CRITICAL'
        },
        'NVDA': {
            'primary_demand_drivers': [
                'Microsoft', 'Google', 'Alphabet', 'Amazon', 'AWS',
                'Meta', 'Oracle', 'OpenAI'
            ],
            'thesis_enablers': ['TSMC', 'AI inference demand', 'Blackwell adoption'],
            'regulatory_counterparties': ['BIS', 'Senate Commerce', 'EU antitrust'],
            'alert_sensitivity': 'CRITICAL'
        },
        # ... remaining positions follow same pattern
    }

    # Alert sensitivity levels
    ALERT_SENSITIVITY = {
        'CRITICAL': ['LEGAL_RULING', 'REGULATORY_FILING',
                     'EARNINGS_WARNING', 'MA_ANNOUNCEMENT'],
        'HIGH':     ['LEADERSHIP_CHANGE', 'CREDIT_EVENT'],
        'MEDIUM':   ['PARTNERSHIP_CHANGE', 'PRODUCT_DELAY']
    }
```

1.5 Daily Monitor Integration

CDM adds two elements to the daily monitor. The first is a cross-reference panel in the equity book section — each position shows its named dependency alert status alongside its price and flag badges. The second is a dedicated CDM alert in the alerts section when a CRITICAL or HIGH event fires.

Equity book column added	Dependency status badge: CLEAR (green) / WATCH (amber) / ALERT (red) based on most severe active CDM signal for that position
Alert format	'CDM ALERT: [NAMED ENTITY] [EVENT TYPE] — affects [N] positions: [TICKER LIST]. TDC thesis review queued.'
Alert severity mapping	LEGAL_RULING → DANGER alert · REGULATORY_FILING → WARNING alert · EARNINGS_WARNING → WARNING alert
Session log	Every CDM propagation event logged with: entity name, event type, source URL, positions affected, timestamp, severity classification

MODULE D — THESIS DEPENDENCY CHECKER

TDC — Continuous Thesis Integrity Auditing

2. Module D Overview

File	src/engine/tdc.py — new module
Tier classification	Tier 1 — system queues SENTINEL adversarial review. PM has 24-hour response window. Silence = system logs as 'thesis confirmed by non-response' and continues monitoring.
Build time	2-3 days — requires Claude API integration (already specified in FSD v1.1 Section 11) and CDM as upstream input
Dependencies	CDM (Module C) propagation signals · Claude API wrapper (src/intelligence/claude_wrapper.py) · position_dependency_map.py · session log · SENTINEL gate records for each position
Ongoing cost	~$0.30-0.50 per thesis review call to Claude API. Estimated 5-10 reviews per week at steady state = ~$10-20/month incremental API cost
Runs on	Two triggers: (1) CDM propagation signal received (immediate), (2) Weekly scheduled audit every Monday alongside Systematic Scan Engine
Key distinction	TDC does not evaluate price performance. It evaluates thesis integrity — whether the original reasons for owning a position are still structurally intact. A position can be performing well on price while its thesis is quietly being undermined. TDC catches the thesis deterioration before it becomes price deterioration.

2.1 The Two TDC Triggers

Trigger 1 — CDM propagation (immediate)

When CDM fires a CRITICAL or HIGH alert, TDC receives the signal and immediately runs a thesis integrity review for every affected position. This is the reactive layer — it responds to known events as soon as they are detected.

The review asks a single structured question via the Claude API: given this specific development affecting [NAMED ENTITY], does the original thesis for [POSITION] remain intact? The API call includes the original SENTINEL gate records for the position, the current CDM event description, and the three most relevant documents from the knowledge base. It returns a structured JSON response with a thesis integrity score and a specific bear case articulation if the score falls below the threshold.

Trigger 2 — Weekly scheduled audit (proactive)

Every Monday at 6AM CT, TDC runs a scheduled thesis integrity audit on every position in the book — regardless of whether CDM has fired. This is the proactive layer. It catches slow-moving thesis deterioration that no single news event triggers but that accumulates over time: a named customer quietly reducing AI capex in earnings calls, a regulatory posture shifting in a series of small rulings, a technology platform trend moving against the thesis.

The weekly audit pulls the last 7 days of news and filings relevant to each position's named dependencies and asks: has anything in the past 7 days provided evidence that weakens any of the original SENTINEL gate assumptions for this position? This is the continuous SENTINEL adversarial cross-examination that the manual system only runs episodically.

2.2 Thesis Integrity Score

TDC produces a Thesis Integrity Score (TIS) for each position on every review. The TIS is distinct from the MICS conviction score. MICS measures entry quality. TIS measures ongoing thesis validity.

TIS range	Label	ARMS response	Meaning
8.0 – 10.0	INTACT	No action. Log result. Continue monitoring.	All original thesis assumptions confirmed by current data. No new bear case evidence.
6.0 – 7.9	WATCH	Position flag upgraded to WATCH if not already. PM notified in daily monitor.	One or more thesis assumptions have weakened but not broken. Bear case evidence present but not conclusive.
4.0 – 5.9	IMPAIRED	SENTINEL adversarial review queued as Tier 1 action. PM has 24 hours to respond.	Multiple thesis assumptions weakened. Bear case evidence present and specific. Conviction reaffirmation or position review required.
0.0 – 3.9	BROKEN	CDF accelerated review triggered. SENTINEL full re-run queued. PM decision required within 24 hours.	Original thesis no longer supportable by available evidence. Position requires immediate review and probable exit planning.

IMPORTANT: TIS IMPAIRED or BROKEN does not automatically trigger a sell order. It triggers a mandatory human review because thesis assessment is a judgment call that requires the PM's pre-consensus intelligence. What TIS cannot know is whether the PM has new Category A information — a direct conversation with a company insider, a pattern recognition from prior cycles — that explains why the thesis remains intact despite the surface-level evidence. TDC surfaces the question. The PM answers it.

2.3 Claude API Call Specification

Every TDC review routes through the existing Claude API wrapper (src/intelligence/claude_wrapper.py). The prompt is structured to return parseable JSON.

```
def run_thesis_review(position: str,
                      event_description: str,
                      sentinel_gates: Dict,
                      knowledge_context: List[str]) -> ThesisReviewResult:

    prompt = f'''
    You are running a thesis integrity review for position {position}.

    ORIGINAL SENTINEL GATE RECORDS:
    {json.dumps(sentinel_gates, indent=2)}

    CURRENT DEVELOPMENT:
    {event_description}

    RELEVANT CONTEXT FROM KNOWLEDGE BASE:
    {chr(10).join(knowledge_context)}

    Evaluate whether the original thesis remains intact.
    Return ONLY valid JSON with this exact structure:
    {{
        'tis_score': <float 0.0-10.0>,
        'tis_label': <'INTACT'|'WATCH'|'IMPAIRED'|'BROKEN'>,
        'gates_affected': [<list of gate numbers with weakened assumptions>],
        'bear_case_evidence': <specific evidence string or null>,
        'bull_case_rebuttal': <why thesis may still hold despite evidence>,
        'recommended_action': <'MONITOR'|'WATCH_FLAG'|'PM_REVIEW'|'URGENT_REVIEW'>
    }}
    '''

    response = claude_wrapper.call(
        task_type='thesis_review',
        prompt=prompt,
        knowledge_base_query=f'{position} thesis SENTINEL gates'
    )

    result = json.loads(response)
    return ThesisReviewResult(**result, position=position,
                              reviewed_at=datetime.utcnow().isoformat())
```

2.4 The Google-MU Case Study — How TDC Would Have Worked

Continue the CDM case study through TDC to show the complete signal-to-action chain.

Continuing from Section 1.3: CDM has propagated a CRITICAL alert to MU citing Google antitrust proceedings. TDC receives the signal and runs immediately.

8. TDC retrieves MU's original SENTINEL gate records from the knowledge base. Key Gate 2 record: 'HBM memory is non-optional for AI training at scale. Primary buyers: Microsoft, Google, Amazon, Meta. No substitution available at current HBM3E performance specifications.'
9. TDC retrieves the CDM event description: 'DOJ pursuing structural remedies against Google/Alphabet including potential Chrome divestiture and default search agreement restrictions. Legal proceedings ongoing with 12-24 month resolution timeline.'
10. TDC runs Claude API thesis review. The model assesses: does potential Google capex impairment materially weaken the Gate 2 non-optional thesis for MU?
11. API response: TIS score 6.2 — WATCH. Gates affected: [Gate 2]. Bear case evidence: 'Google represents approximately 15-20% of HBM demand. Legal proceedings creating capex uncertainty. Other hyperscalers (Microsoft, Amazon) likely absorb partial slack but full demand replacement not guaranteed.' Bull case rebuttal: 'AI training demand is supply-constrained, not demand-constrained at current scale. Google impairment of 15-20% demand may be offset by Amazon and Microsoft acceleration.'
12. TDC upgrades MU flag to WATCH. Logs TIS score 6.2 with full review record to session log.
13. Daily monitor surfaces: 'TDC WATCH: MU thesis integrity 6.2/10. Google antitrust proceedings affect named demand driver. Gate 2 assumption partially weakened. Bear case: HBM demand concentration risk elevated. Bull case: remaining hyperscaler absorption likely sufficient. PM review recommended.'

The PM now has a specific, structured, evidence-based thesis integrity assessment rather than a price alert or a generic flag. The decision they make — hold with conviction, reduce weight, or initiate a full SENTINEL re-check — is informed by exactly the right analysis.

2.5 TDC Data Structures

```
@dataclass class ThesisReviewResult:
    position: str
    tis_score: float              # 0.0 - 10.0
    tis_label: str                # INTACT | WATCH | IMPAIRED | BROKEN
    gates_affected: List[int]     # SENTINEL gate numbers
    bear_case_evidence: str       # specific evidence text or None
    bull_case_rebuttal: str       # why thesis may still hold
    recommended_action: str       # MONITOR | WATCH_FLAG | PM_REVIEW | URGENT
    trigger_type: str             # 'CDM_PROPAGATION' | 'WEEKLY_AUDIT'
    trigger_entity: str           # named entity that triggered review
    reviewed_at: str              # ISO timestamp
    api_cost_usd: float           # logged for monthly cost tracking

@dataclass class TDCStatus:
    last_weekly_audit: str        # ISO date of last full audit
    positions_at_watch: List[str] # positions currently TIS WATCH
    positions_impaired: List[str] # positions currently TIS IMPAIRED
```

```
    positions_broken: List[str]   # positions currently TIS BROKEN
    pending_pm_reviews: int       # Tier 1 actions awaiting PM response
    last_cdm_propagation: str     # ISO timestamp of last CDM alert
```

2.6 The Insider Selling Trigger — Closing the ALAB Gap

The ALAB situation identified a second related gap: CEO insider selling is Category A bear case evidence in the SENTINEL framework but was not a named first-class signal in any ARMS module. CDM and TDC together close this gap.

Josh should add SEC Form 4 filings to the CDM named entity event types. When a CEO or CFO of a portfolio company files a Form 4 disclosing open-market sales above a defined threshold — proposed: $50,000 for C-suite open-market sales, excluding pre-planned 10b5-1 sales — CDM fires a HIGH alert and TDC runs an immediate thesis review for that position.

Form 4 data source	SEC EDGAR full-text search API — free. Specify Form 4 filings for tickers in the book. File within 2 business days of transaction.
Insider sale threshold	Open-market sales >$50,000 by CEO or CFO. 10b5-1 pre-planned sales excluded — less informative signal.
CDF acceleration	Insider sale above threshold triggers a 21-day accelerated CDF review window. Not an automatic sell. An accelerated review clock.
TDC response	Insider sale classified as HIGH severity. TDC runs thesis review within 6 hours. Bear case evidence field explicitly populated with insider sale details.
ALAB application	The CEO insider selling that was flagged manually in the daily monitor for four consecutive days would have been caught and reviewed automatically on day one under this specification.

```
# Add to CDM event type classification:
'INSIDER_SALE': {
    'severity': 'HIGH',
    'threshold_usd': 50000,
    'roles': ['CEO', 'CFO', 'President'],
    'exclude_10b5_1': True,
    'cdf_acceleration_days': 21,
    'tdc_review_hours': 6
}
```

3. Combined Build Plan for Josh

Build Module C (CDM) first — it is the data layer. Module D (TDC) depends on it. Both are buildable within one week total.

Module	Build time	Priority	Files	Milestone
Module C CDM	1 day	Build first	src/config/position_dependency_map.py (new) src/engine/cdm.py (new)	Named entity alerts propagating to all dependent positions. GOOG antitrust event would fire on NVDA, AMD, MU, ALAB, ANET, AVGO, MRVL simultaneously.
Module D TDC	2-3 days	Build second	src/engine/tdc.py (new)	First automated thesis integrity review runs. MU Google scenario produces TIS score with specific bear case evidence. Insider sale Form 4 triggers ALAB CDF acceleration.

3.1 Testing Protocol — Module C (CDM)

14. Seed the news feed with the Google antitrust article from March 26, 2026. Verify CDM identifies 'Google' and 'Alphabet' as named entities. Verify it propagates alerts to NVDA, AMD, MU, ALAB, ANET, AVGO, and MRVL. Verify TSLA, PLTR, ETN, and VRT do not receive alerts.
15. Simulate a Form 4 filing for ALAB CEO with an open-market sale of $75,000. Verify CDM fires a HIGH alert for ALAB only. Verify 10b5-1 sale simulation does not trigger the alert.
16. Simulate a positive event for a named entity — Google announces expanded AI capex. Verify CDM logs it as LOW severity and generates no alert. Verify no TDC review is queued.
17. Verify all CDM events are logged to the session log with entity name, event type, source, affected positions, severity, and timestamp.

3.2 Testing Protocol — Module D (TDC)

18. Trigger a TDC review manually for MU using the Google antitrust event description. Verify the Claude API call returns valid JSON. Verify the TIS score is in the WATCH range (6.0-7.9). Verify the gates_affected field includes Gate 2. Verify the bear_case_evidence field is populated.

19. Trigger a TDC weekly audit for all 12 positions. Verify all positions receive a TIS score. Verify the audit completes within 30 minutes. Verify total API cost is below $6 for a full 12-position audit.
20. Simulate a BROKEN thesis scenario (TIS < 4.0). Verify CDF accelerated review is triggered. Verify PM review is queued as Tier 1 action with 24-hour window. Verify the session log captures the full review record.
21. Allow a Tier 1 PM review window to expire with no response. Verify the session log records 'thesis confirmed by non-response' — not an execution action. TDC is advisory. It never executes a trade.

3.3 Updated File Structure

File	Status	Change
src/config/position_dependency_map.py	NEW	Named entity dependency map for all 12 current positions. PM-maintained. Updated on every SENTINEL entry or exit.
src/engine/cdm.py	NEW	Customer Dependency Map module. Named entity recognition, event classification, alert propagation to dependent positions.
src/engine/tdc.py	NEW	Thesis Dependency Checker. Claude API thesis integrity reviews on CDM propagation and weekly schedule. TIS scoring and flag management.
src/intelligence/claude_wrapper.py	UPDATED	Add 'thesis_review' as a new task_type. Add TDC-specific prompt template.
src/reporting/daily_monitor.py	UPDATED	CDM dependency status badge added to equity book table. TDC TIS score added to position status. CDM/TDC alerts added to alerts section.
src/execution/confirmation_queue.py	UPDATED	TDC PM review requests added as a new Tier 1 action type with 24-hour window.

3.4 What Disappears From Human Responsibility After These Modules Are Built

This is the measure of the blade sharpening. After CDM and TDC are live, the following are no longer the PM's responsibility to catch manually:

- Cross-sector signal propagation — a legal ruling against a named entity automatically reaches every dependent position within 30 minutes.
- Thesis integrity monitoring — every position is audited weekly against its original SENTINEL gate assumptions. Deterioration is flagged before it becomes price deterioration.

- Insider selling detection — Form 4 filings trigger automatic CDM alerts and CDF acceleration. The four-day ALAB delay becomes a same-day detection.
- Hyperscaler capex monitoring — earnings warnings from Microsoft, Google, Amazon, or Meta automatically propagate to every position in the book with exposure to that entity.
- Regulatory event monitoring — DOJ filings, BIS export control rulemakings, SEC investigations — all monitored against named counterparties and propagated to dependent positions automatically.

What remains the PM's responsibility: providing the pre-consensus intelligence — the Category A knowledge from direct conversations, the 28-year pattern recognition — that the system cannot generate. The PM's job is the insight that precedes the data. The system's job is everything that follows it.

The gap that allowed the Google-MU connection to be missed is now closed. The system catches what the PM should not have to catch.

"The system catches what the PM should not have to catch."

Achelion Capital Management, LLC · Flow. Illumination. Discipline. Conviction.
